The first and probably the greatest is that while lunar distances must be computed for each and every year, the method here proposed suffices, with the assistance of simple and easily constructed tables, for an indefinite number of years before or after any epoch that may be chosen, and the only quantities that are to be taken from the ephemeris are already given therein for other purposes. Second, the required observations are fewer and more easily taken than those for the ordinary method, an interval of even an hour being admissible for the purpose of making them. Third, the process of computation tends to greatly reduce instrumental or observational errors, by reason of a smaller quantity being deduced from a larger, and on account of the fact that the observed distances will lie opposite sides of the moon. Fourth, it does not require any knowledge whatever of the Greenwich time, or of the longitude, and only an approximate knowledge of the latitude, and is thus, in one sense, an absolute method. This method is as short and easy as that of the ordinary Lunar Distance. The process is about the same as that just given, differing mainly in this, that instead of the star places being the apparent ones for the time of the observation, they are the mean places for any chosen epoch. Thus the right ascensions and the polar distances and the trigonometrical functions thereof, which are required...
